Digestive structures: learning reference

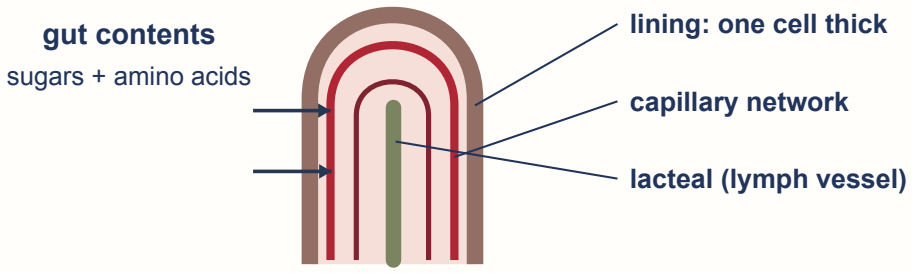

Schematic front view, not to scale. Follow the thick continuous food canal; narrow ducts carry secretions.

Continuous canal: food route · dashed arrows: secretions

Food route: mouth → oesophagus → stomach → small intestine → large intestine → rectum → anus.
Food does not enter the liver, gall bladder or pancreas. Their secretions enter the small intestine.

A villus: structure helps absorption

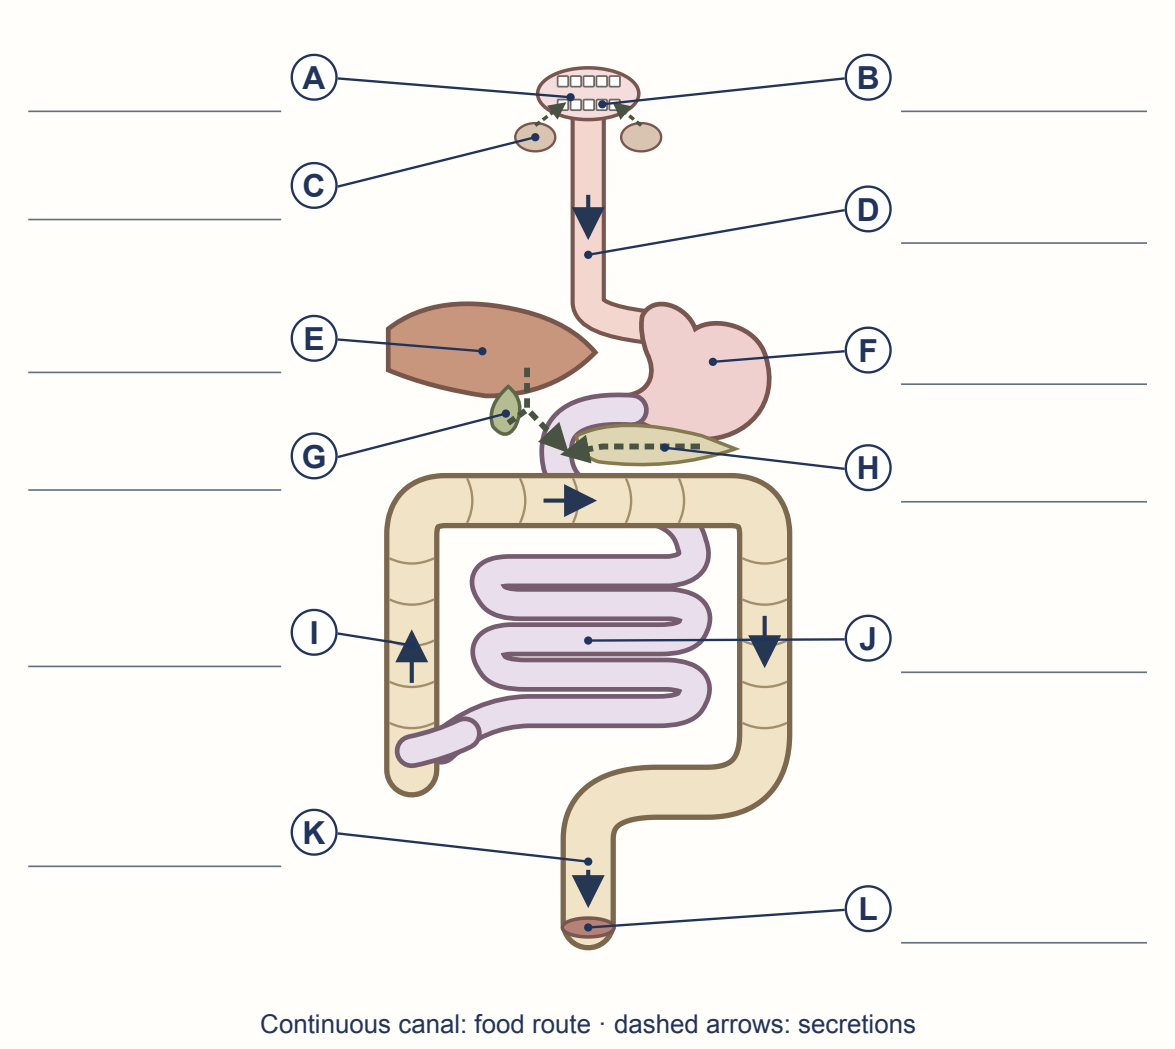

Many villi: large surface for absorption.
Thin lining: short crossing distance.
Blood supply: carries products away.

Enzyme → food → final products
Carbohydrases → starch → small sugars.
Proteases → protein → amino acids.
Lipase → lipids → fatty acids + glycerol.

Structures: practise and explain

Write the names on the A–L leader lines. Turn over the reference while retrieving; check after your attempt.

Continuous canal: food route · dashed arrows: secretions

1. Food route: use organ names, from mouth to anus.

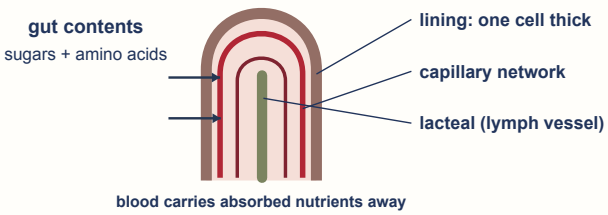

2. State one job for each: C, H and G.

C:

H:

G:

3. This is one villus. Explain how its thin lining helps absorption.

Success: correct organ names and route; accurate structure→action links; a feature linked to its effect. Keep first answers, then improve the exact gap.
